# Building a Logging Pipeline on AWS

#### **The Goal**

Debug issues that may have happened days or even weeks previously, and which may involve multiple services in a distributed architecture.

## You use logging, right?

2018-03-12 11:30:28,243 [http-bio-9966-exec-1] DEBUG ClinicServiceImpl - findOwnerById(1) 2018-03-12 11:30:44,148 [http-bio-9966-exec-4] DEBUG ClinicServiceImpl - findOwnerById(1) 2018-03-12 11:30:44,154 [http-bio-9966-exec-4] DEBUG ClinicServiceImpl - findOwnerById(1) 2018-03-12 11:31:14,972 [http-bio-9966-exec-2] DEBUG ClinicServiceImpl - findOwnerById(1) 2018-03-12 11:31:14,977 [http-bio-9966-exec-2] DEBUG ClinicServiceImpl - findPetTypes() 2018-03-12 11:31:14,984 [http-bio-9966-exec-2] DEBUG ClinicServiceImpl - findPetTypes() 2018-03-12 11:31:14,984 [http-bio-9966-exec-2] DEBUG ClinicServiceImpl - savePet(pumpkin cheeks) 2018-03-12 11:31:15,029 [http-bio-9966-exec-2] DEBUG ClinicServiceImpl - findOwnerById(1) 2018-03-12 11:31:16,300 [http-bio-9966-exec-1] DEBUG ClinicServiceImpl - findOwnerById(19) 2018-03-12 11:34:16,449 [http-bio-9966-exec-1] WARN ClinicServiceImpl - findOwnerById: invalid ID 19

## The problems with local logging

Have to go to the machine to see logs (or retrieve with scp/rsync)

Limited ability to extract information (grep is your only friend)

No correlation of events from multiple sources

Logfiles disappear when machine shuts down

## **Options for Centralized Logging**

## **Shared Drive**

NFS (EFS) mount, with application-specific sub-directories

Alternative: copy logfiles to S3

Pros:

• Applications don't need to be changed

- Limited ability to examine/correlate logfiles
- Management can be challenging, especially in auto-scaled deployment

## Syslog

The logging daemon that comes with Linux

Processes send UDP messages to a daemon (either local or remote)

Pros:

- Library support for most major languages (or roll your own)
- Can integrate with many third-party applications

- Limited ability to customize output
- Need an agent/configuration on each machine
- Sending messages requires a context switch

## **CloudWatch Logs**

AWS managed service that aggregates logs by group and stream

Pros:

- Default destination for Lambda, Batch, many other services
- CloudWatch Logs Insights can be used to search, correlate

- Must install/configure agent on EC2 instances
- No built-in support for associating instance information with logging events
- Each line of the file is sent as a separate logging event
- Search features aren't that good

## **External Service Providers**

Several companies provide Log Management as a Service: they ingest your logs, store them in a search engine, and provide you a variety of ways to analyze.

Pros:

- Nothing to manage locally (other than feeding the logs to the service)
- Can ingest many different formats
- Wide variety of analytics tools, including machine learning

- Cost ratchets up quickly depending on volume and storage duration
- Not all plans support archives
- Log data is not under your control

## Logstash / Elasticsearch / Kibana

The standard "roll your own" solution: Logstash parses logfiles and sends them to Elasticsearch, Kibana provides analytics.

Pros:

- Search-engine-based log analysis/correlation
- Can find pre-built parsers for standard logging formats

- Must install/configure agent
- "Roll your own" means you deploy and maintain

## **An AWS-Centric Alternative**

## Kinesis / Firehose / AWS Elasticsearch / Kibana

A homegrown solution that leverages several AWS services.

Pros:

- Amazon manages the components -- It Just Works™
- Scalable: configure each component to match volumes
- Can use Lambda functions to parse arbitrary messages
- Easy to archive messages (on S3)
- Kinesis stream can service multiple destinations

- More expensive than fully-managed solutions at small scales
- Still some management required (cleanup of old indexes)
- Must provide logging events to Elasticsearch in JSON

## **Applications Write Log Output in JSON**

```
"hostname": "ithilien",
"level": "DEBUG",
"logger": "org.springframework.samples.petclinic.service.ClinicServiceImpl",
"message": "findOwnerByLastName(franklin)",
"processId": "5971",
"tags": {
    "appName": "Example",
    "deployment": "prod"
},
"thread": "http-bio-9966-exec-4",
"timestamp": "2018-03-12T15:41:31.564Z"
```

#### **Messages Stored in Kinesis Stream**

Each shard accepts up to 1,000 messages per second, stores for 24 hours

• Charged by shard-hour, plus additional charge per million messages

Shameless plug: for Java, use <u>https://github.com/kdgregory/log4j-aws-appenders</u>

• Appender library for Log4J 1.x and Logback (Log4J 2.x Real Soon Now™)

Other libraries for other languages, or use Kinesis Agent from AWSLabs

## **Kinesis Firehose Aggregates Messages**

Aggregates messages based on either time or size

- For logging, time is most important, although there's always a lag
- For archives, size is important: S3-IA requires minimum 128k

Can write same messages to S3

• Useful for long-term archival storage

Alternate destination: Splunk

## **Sizing and Costs**

Description	Unit Cost	Monthly Cost
Kinesis Streams		
8 shards	0.02 / hour	87.84
100 MM payload units/day (est)	0.014 / MM units	42.70
Kinesis Firehose		
100 MM records/day (est)	0.029 / MM records	88.45
S3 Backup		
1 GB/day IA (est)	0.013 / GB / Month	0.38
1 GB/day Standard (est)	0.023 / GB / Month	0.70
Elasticsearch Cluster		
6 m4.large instance	0.15 / hour	663.19
512 GB storage/node (SSD)	0.135 / GB / Month	414.72
Total		1,297.98

## **ELB Access Logs**

## **Overview**

Every request is logged, whether or not successful

Logs are written to S3, organized by date/time

• Can choose whether to write every hour or every five minutes

Multiple tools available to analyze

- Simple queries via AWS Athena
- Plugins for Logstash, Loggly, Splunk, ...

Home-grown solution: Lambda to parse logs, write to Elasticsearch

- Triggered every time a logfile is written to S3
- Will extract details from URL

## Log Format (Classic ELB)

example  $\leftarrow$  load balancer name

173.49.123.456:58798 172.30.1.119:80 ← source and destination IPs

0.000037 0.001039 0.000046  $\leftarrow$  elapsed time for ELB, back-end service

200 200 0 43862  $\leftarrow$  HTTP status codes, request/response size

"curl/7.47.0" ⇐ user agent

 $\sim$   $\sim$  SSL cipher/protocol

#### **Example: Top 10 Pages**

## **CloudWatch Metrics**

## **Overview**

Time-series dimensioned metrics

- Most AWS services have a set of predefined metrics
- Example: free storage space by database instance

May be used to trigger alarms

• Which in turn can trigger auto-scaling

Applications can write custom metrics

• Example: request processing time by URL

Custom metrics are charged per metric, per month

• A "metric" is a specific combination of dimensions

#### Example
